Up to this degree heating increases the susceptibility; and at this degree of heat it is many times greater than in cold wrought iron. But at higher temperatures a sudden loss of magnetic susceptibility takes place; and at 786 degrees it practically vanishes. In brief, there is a critical temperature. for magnetic susceptibility. In 1897, Dr. D. K. Morris prosecuted a series of experiments along the same line as those of Hopkinson, and through a wider range; and he found that the increment of susceptibility is not constant up to the critical temperature. In three specimens with which he made tests the rise was rapid to 300 degrees centigrade. Between 400 degrees and 500 degrees it was constant. Thence to 750 the rise was again rapid, reaching a very high value. For these specimens 770 degrees, 780 degrees, and 795 degrees were the several critical temperatures found. From these tests and those of Hopkinson, the inference is that impurities and different degrees of hardness affected the results, and will always do so. In fact, Isaac T. Osmond, an American, a graduate of Cornell, found that in hard steel there is a wider difference between magnetic and non-magnetic conditions at the critical temperature. Since etheric agitation which causes heat causes also a state of strain tending to rend the molecules asunder, the facts just enumerated furnish an interesting transition from the subject of the influence of heat on magnetization to that...
